Aggregations operations process data records and return computed results. Aggregation operations group values from multiple documents together, and can perform a variety of operations on the grouped data to return a single result. MongoDB provides three ways to perform aggregation: the aggregation pipeline (page 7), the map-reduce function (page 10), and single purpose aggregation methods and commands (page 12).

Aggregation Introduction (page 3) A high-level introduction to aggregation.

Aggregation Concepts (page 7) Introduces the use and operation of the data aggregation modalities available in MongoDB.

Aggregation Pipeline (page 7) The aggregation pipeline is a framework for performing aggregation tasks, modeled on the concept of data processing pipelines. Using this framework, MongoDB passes the documents of a single collection through a pipeline. The pipeline transforms the documents into aggregated results, and is accessed through the aggregate database command.
Map-Reduce (page 10) Map-reduce is a generic multi-phase data aggregation modality for processing quantities of data. MongoDB provides map-reduce with the mapReduce database command.

Single Purpose Aggregation Operations (page 12) MongoDB provides a collection of specific data aggregation operations to support a number of common data aggregation functions. These operations include returning counts of documents, distinct values of a field, and simple grouping operations.

Aggregation Examples (page 20) Examples and tutorials for data aggregation operations in MongoDB.

Aggregation Reference (page 37) References for all aggregation operations material for all data aggregation methods in MongoDB.

1 Aggregation Introduction

Aggregations are operations that process data records and return computed results. MongoDB provides a rich set of aggregation operations that examine and perform calculations on the data sets. Running data aggregation on the mongod instance simplifies application code and limits resource requirements.

Like queries, aggregation operations in MongoDB use collections of documents as an input and return results in the form of one or more documents.

1.1 Aggregation Modalities

Aggregation Pipelines

MongoDB 2.2 introduced a new aggregation framework (page 7), modeled on the concept of data processing pipelines. Documents enter a multi-stage pipeline that transforms the documents into an aggregated result.

The most basic pipeline stages provide filters that operate like queries and document transformations that modify the form of the output document.

Other pipeline operations provide tools for grouping and sorting documents by specific field or fields as well as tools for aggregating the contents of arrays, including arrays of documents. In addition, pipeline stages can use operators for tasks such as calculating the average or concatenating a string.

The pipeline provides efficient data aggregation using native operations within MongoDB, and is the preferred method for data aggregation in MongoDB.

Map-Reduce

MongoDB also provides map-reduce (page 10) operations to perform aggregation. In general, map-reduce operations have two phases: a map stage that processes each document and emits one or more objects for each input document, and reduce phase that combines the output of the map operation. Optionally, map-reduce can have a finalize stage to make final modifications to the result. Like other aggregation operations, map-reduce can specify a query condition to select the input documents as well as sort and limit the results.

Map-reduce uses custom JavaScript functions to perform the map and reduce operations, as well as the optional finalize operation. While the custom JavaScript provide great flexibility compared to the aggregation pipeline, in general, map-reduce is less efficient and more complex than the aggregation pipeline.

Note: Starting in MongoDB 2.4, certain mongo shell functions and properties are inaccessible in map-reduce op-
db.orders.aggregate([
  {$match: { status: "A" }}
  {$group: { _id: "$cust_id", total: { $sum: "$amount" } } } ]
)

Collection

orders

$match stage

$group stage

Results

{ _id: "A123",
  total: 750
}

{ _id: "B212",
  total: 200
}

{ cust_id: "A123",
  amount: 500,
  status: "A"
}

{ cust_id: "A123",
  amount: 250,
  status: "A"
}

{ cust_id: "B212",
  amount: 200,
  status: "A"
}

{ cust_id: "A123",
  amount: 300,
  status: "D"
}
MongoDB 2.4 also provides support for multiple JavaScript operations to run at the same time. Before MongoDB 2.4, JavaScript code executed in a single thread, raising concurrency issues for map-reduce.

```javascript
Collection

db.orders.mapReduce(
    map -> function() { emit( this.cust_id, this.amount ); },
    reduce -> function(key, values) { return Array.sum( values ) },
    query -> { status: "A" },
    out: "order_totals"
)
```

### Single Purpose Aggregation Operations

For a number of common single purpose aggregation operations (page 12), MongoDB provides special purpose database commands. These common aggregation operations are: returning a count of matching documents, returning the distinct values for a field, and grouping data based on the values of a field. All of these operations aggregate documents from a single collection. While these operations provide simple access to common aggregation processes, they lack the flexibility and capabilities of the aggregation pipeline and map-reduce.

### 1.2 Additional Features and Behaviors

Both the aggregation pipeline and map-reduce can operate on a sharded collection. Map-reduce operations can also output to a sharded collection. See Aggregation Pipeline and Sharded Collections (page 18) and Map-Reduce and Sharded Collections (page 19) for details.
db.orders.distinct("cust_id")

```json
{
  cust_id: "A123",
  amount: 500,
  status: "A"
}

{
  cust_id: "A123",
  amount: 250,
  status: "A"
}

{
  cust_id: "B212",
  amount: 200,
  status: "A"
}

{
  cust_id: "A123",
  amount: 300,
  status: "D"
}
```

distinct [ "A123", "B212" ]
The aggregation pipeline can use indexes to improve its performance during some of its stages. In addition, the aggregation pipeline has an internal optimization phase. See *Pipeline Operators and Indexes* (page 9) and *Aggregation Pipeline Optimization* (page 15) for details.

For a feature comparison of the aggregation pipeline, map-reduce, and the special group functionality, see *Aggregation Commands Comparison* (page 42).

### 2 Aggregation Concepts

MongoDB provides the three approaches to aggregation, each with its own strengths and purposes for a given situation. This section describes these approaches and also describes behaviors and limitations specific to each approach. See also the *chart* (page 42) that compares the approaches.

**Aggregation Pipeline (page 7)** The aggregation pipeline is a framework for performing aggregation tasks, modeled on the concept of data processing pipelines. Using this framework, MongoDB passes the documents of a single collection through a pipeline. The pipeline transforms the documents into aggregated results, and is accessed through the *aggregate* database command.

**Map-Reduce (page 10)** Map-reduce is a generic multi-phase data aggregation modality for processing quantities of data. MongoDB provides map-reduce with the *mapReduce* database command.

**Single Purpose Aggregation Operations (page 12)** MongoDB provides a collection of specific data aggregation operations to support a number of common data aggregation functions. These operations include returning counts of documents, distinct values of a field, and simple grouping operations.

**Aggregation Mechanics (page 14)** Details internal optimization operations, limits, support for sharded collections, and concurrency concerns.

#### 2.1 Aggregation Pipeline

New in version 2.2.

The aggregation pipeline is a framework for data aggregation modeled on the concept of data processing pipelines. Documents enter a multi-stage pipeline that transforms the documents into an aggregated results.

The aggregation pipeline provides an alternative to *map-reduce* and may be the preferred solution for aggregation tasks where the complexity of map-reduce may be unwarranted.

[^3]: [https://www.mongodb.com/presentations/aggregation-framework-0?jmp=docs](https://www.mongodb.com/presentations/aggregation-framework-0?jmp=docs)
```javascript
db.orders.aggregate([
  {$match: { status: "A" }},
  {$group: { _id: "$cust_id", total: { $sum: "$amount" } }}
])
```

Collection

```
orders
```

$match stage

```
{
cust_id: "A123",
  amount: 500,
  status: "A"
}
```

```
{
cust_id: "A123",
  amount: 250,
  status: "A"
}
```

```
{
cust_id: "B212",
  amount: 200,
  status: "A"
}
```

$group stage

```
{
cust_id: "A123",
  amount: 500,
  status: "A"
}
```

```
{
cust_id: "A123",
  amount: 250,
  status: "A"
}
```

```
{
cust_id: "B212",
  amount: 200,
  status: "A"
}
```

Results

```
{
  _id: "A123",
  total: 750
}
```

```
{
  _id: "B212",
  total: 200
}
```
Aggregation pipeline have some limitations on value types and result size. See *Aggregation Pipeline Limits* (page 18) for details on limits and restrictions on the aggregation pipeline.

**Pipeline**

The MongoDB aggregation pipeline consists of *stages*. Each stage transforms the documents as they pass through the pipeline. Pipeline stages do not need to produce one output document for every input document; e.g., some stages may generate new documents or filter out documents. Pipeline stages can appear multiple times in the pipeline.

MongoDB provides the `db.collection.aggregate()` method in the `mongo` shell and the `aggregate` command for aggregation pipeline. See *aggregation-pipeline-operator-reference* for the available stages.

For example usage of the aggregation pipeline, consider *Aggregation with User Preference Data* (page 24) and *Aggregation with the Zip Code Data Set* (page 21).

**Pipeline Expressions**

Some pipeline stages takes a pipeline expression as its operand. Pipeline expressions specify the transformation to apply to the input documents. Expressions have a document structure and can contain other *expression* (page 38).

Pipeline expressions can only operate on the current document in the pipeline and cannot refer to data from other documents: expression operations provide in-memory transformation of documents.

Generally, expressions are stateless and are only evaluated when seen by the aggregation process with one exception: *accumulator* expressions.

The accumulators, used with the `$group` pipeline operator, maintain their state (e.g. totals, maximums, minimums, and related data) as documents progress through the pipeline.

For more information on expressions, see *Expressions* (page 38).

**Aggregation Pipeline Behavior**

In MongoDB, the `aggregate` command operates on a single collection, logically passing the *entire* collection into the aggregation pipeline. To optimize the operation, wherever possible, use the following strategies to avoid scanning the entire collection.

**Pipeline Operators and Indexes**

The `$match` and `$sort` pipeline operators can take advantage of an index when they occur at the *beginning* of the pipeline.

New in version 2.4: The `$geoNear` pipeline operator takes advantage of a geospatial index. When using `$geoNear`, the `$geoNear` pipeline operation must appear as the first stage in an aggregation pipeline.

Even when the pipeline uses an index, aggregation still requires access to the actual documents; i.e. indexes cannot fully cover an aggregation pipeline.

Changed in version 2.6: In previous versions, for very select use cases, an index could cover a pipeline.

**Early Filtering**

If your aggregation operation requires only a subset of the data in a collection, use the `$match`, `$limit`, and `$skip` stages to restrict the documents that enter at the beginning of the pipeline. When placed at the beginning of a pipeline, `$match` operations use suitable indexes to scan only the matching documents in a collection.
Placing a $match pipeline stage followed by a $sort stage at the start of the pipeline is logically equivalent to a single query with a sort and can use an index. When possible, place $match operators at the beginning of the pipeline.

**Additional Features**

The aggregation pipeline has an internal optimization phase that provides improved performance for certain sequences of operators. For details, see *Aggregation Pipeline Optimization* (page 15).

The aggregation pipeline supports operations on sharded collections. See *Aggregation Pipeline and Sharded Collections* (page 18).

### 2.2 Map-Reduce

Map-reduce is a data processing paradigm for condensing large volumes of data into useful *aggregated* results. For map-reduce operations, MongoDB provides the `mapReduce` database command.

Consider the following map-reduce operation:

In this map-reduce operation, MongoDB applies the *map* phase to each input document (i.e. the documents in the collection that match the query condition). The map function emits key-value pairs. For those keys that have multiple values, MongoDB applies the *reduce* phase, which collects and condenses the aggregated data. MongoDB then stores the results in a collection. Optionally, the output of the reduce function may pass through a *finalize* function to further condense or process the results of the aggregation.

All map-reduce functions in MongoDB are JavaScript and run within the mongod process. Map-reduce operations take the documents of a single *collection* as the *input* and can perform any arbitrary sorting and limiting before beginning the map stage. `mapReduce` can return the results of a map-reduce operation as a document, or may write the results to collections. The input and the output collections may be sharded.

**Note:** For most aggregation operations, the *Aggregation Pipeline* (page 7) provides better performance and more coherent interface. However, map-reduce operations provide some flexibility that is not presently available in the aggregation pipeline.

[^8]: https://www.mongodb.com/presentations/aggregation-framework-0?jmp=docs
```javascript
Collection

db.orders.mapReduce(
  map: function() { emit( this.cust_id, this.amount ); },
  reduce: function(key, values) { return Array.sum( values ); },
  query: { status: "A" },
  out: "order_totals"
)

orders

{ cust_id: "A123", amount: 500, status: "A" }
{ cust_id: "A123", amount: 500, status: "A" }
{ cust_id: "B212", amount: 200, status: "A" }
{ cust_id: "A123", amount: 300, status: "D" }

query

reduce

map

order_totals

{ id: "A123", value: 750 }
{ id: "B212", value: 200 }
Map-Reduce JavaScript Functions

In MongoDB, map-reduce operations use custom JavaScript functions to map, or associate, values to a key. If a key has multiple values mapped to it, the operation reduces the values for the key to a single object.

The use of custom JavaScript functions provide flexibility to map-reduce operations. For instance, when processing a document, the map function can create more than one key and value mapping or no mapping. Map-reduce operations can also use a custom JavaScript function to make final modifications to the results at the end of the map and reduce operation, such as perform additional calculations.

Map-Reduce Behavior

In MongoDB, the map-reduce operation can write results to a collection or return the results inline. If you write map-reduce output to a collection, you can perform subsequent map-reduce operations on the same input collection that merge replace, merge, or reduce new results with previous results. See mapReduce and Perform Incremental Map-Reduce (page 31) for details and examples.

When returning the results of a map reduce operation inline, the result documents must be within the BSON Document Size limit, which is currently 16 megabytes. For additional information on limits and restrictions on map-reduce operations, see the http://docs.mongodb.org/manual/reference/command/mapReduce reference page.

MongoDB supports map-reduce operations on sharded collections. Map-reduce operations can also output the results to a sharded collection. See Map-Reduce and Sharded Collections (page 19).

2.3 Single Purpose Aggregation Operations

Aggregation refers to a broad class of data manipulation operations that compute a result based on an input and a specific procedure. MongoDB provides a number of aggregation operations that perform specific aggregation operations on a set of data.

Although limited in scope, particularly compared to the aggregation pipeline (page 7) and map-reduce (page 10), these operations provide straightforward semantics for common data processing options.

Count

MongoDB can return a count of the number of documents that match a query. The count command as well as the count() and cursor.count() methods provide access to counts in the mongo shell.

Example

Given a collection named records with only the following documents:

{ a: 1, b: 0 }
{ a: 1, b: 1 }
{ a: 1, b: 4 }
{ a: 2, b: 2 }

The following operation would count all documents in the collection and return the number 4:

```javascript
db.records.count()
```

The following operation will count only the documents where the value of the field a is 1 and return 3:

```javascript
db.records.count({ a: 1 })
```
**Distinct**

The *distinct* operation takes a number of documents that match a query and returns all of the unique values for a field in the matching documents. The *distinct* command and `db.collection.distinct()` method provide this operation in the *mongo* shell. Consider the following examples of a distinct operation:

```
Collection

db.orders.distinct( "cust_id" )
```

```
{
    cust_id: "A123",
    amount: 500,
    status: "A"
}

{
    cust_id: "A123",
    amount: 250,
    status: "A"
}

{
    cust_id: "B212",
    amount: 200,
    status: "A"
}

{
    cust_id: "A123",
    amount: 300,
    status: "D"
}
```

```
orders
```

```
distinct
[ "A123", "B212" ]
```

**Example**

Given a collection named `records` with only the following documents:

```
{ a: 1, b: 0 }
{ a: 1, b: 1 }
{ a: 1, b: 1 }
{ a: 1, b: 4 }
{ a: 2, b: 2 }
{ a: 2, b: 2 }
```

Consider the following `db.collection.distinct()` operation which returns the distinct values of the field `b`:
db.records.distinct( "b" )

The results of this operation would resemble:

[ 0, 1, 4, 2 ]

**Group**

The *group* operation takes a number of documents that match a query, and then collects groups of documents based on the value of a field or fields. It returns an array of documents with computed results for each group of documents.

Access the grouping functionality via the *group* command or the `db.collection.group()` method in the **mongo shell**.

**Warning:** *group* does not support data in sharded collections. In addition, the results of the *group* operation must be no larger than 16 megabytes.

Consider the following group operation:

**Example**

Given a collection named *records* with the following documents:

```json
{ a: 1, count: 4 }
{ a: 1, count: 2 }
{ a: 1, count: 4 }
{ a: 2, count: 3 }
{ a: 2, count: 1 }
{ a: 1, count: 5 }
{ a: 4, count: 4 }
```

Consider the following *group* operation which groups documents by the field *a*, where *a* is less than 3, and sums the field *count* for each group:

```javascript
db.records.group( {
    key: { a: 1 },
    cond: { a: { $lt: 3 } },
    reduce: function(cur, result) { result.count += cur.count },
    initial: { count: 0 }
} )
```

The results of this group operation would resemble the following:

```json
[  
  { a: 1, count: 15 },
  { a: 2, count: 4 }
]
```

**See also:**

The `$group` for related functionality in the *aggregation pipeline* (page 7).

### 2.4 Aggregation Mechanics

This section describes behaviors and limitations for the various aggregation modalities.
Aggregation Pipeline Optimization (page 15) Details the internal optimization of certain pipeline sequence.

Aggregation Pipeline Limits (page 18) Presents limitations on aggregation pipeline operations.

Aggregation Pipeline and Sharded Collections (page 18) Mechanics of aggregation pipeline operations on sharded collections.

Map-Reduce and Sharded Collections (page 19) Mechanics of map-reduce operation with sharded collections.

Map Reduce Concurrency (page 20) Details the locks taken during map-reduce operations.

Aggregation Pipeline Optimization

Aggregation pipeline operations have an optimization phase which attempts to reshape the pipeline for improved performance.

To see how the optimizer transforms a particular aggregation pipeline, include the `explain` option in the `db.collection.aggregate()` method.

Optimizations are subject to change between releases.

Projection Optimization

The aggregation pipeline can determine if it requires only a subset of the fields in the documents to obtain the results. If so, the pipeline will only use those required fields, reducing the amount of data passing through the pipeline.

Pipeline Sequence Optimization

$sort + $match Sequence Optimization When you have a sequence with $sort followed by a $match, the $match moves before the $sort to minimize the number of objects to sort. For example, if the pipeline consists of the following stages:

```
{ $sort: { age : -1 } },
{ $match: { status: 'A' } }
```

During the optimization phase, the optimizer transforms the sequence to the following:

```
{ $match: { status: 'A' } },
{ $sort: { age : -1 } }
```

$skip + $limit Sequence Optimization When you have a sequence with $skip followed by a $limit, the $limit moves before the $skip. With the reordering, the $limit value increases by the $skip amount.

For example, if the pipeline consists of the following stages:

```
{ $skip: 10 },
{ $limit: 5 }
```

During the optimization phase, the optimizer transforms the sequence to the following:

```
{ $limit: 15 },
{ $skip: 10 }
```

This optimization allows for more opportunities for $sort + $limit Coalescence (page 16), such as with $sort + $skip + $limit sequences. See $sort + $limit Coalescence (page 16) for details on the coalescence and $sort + $skip + $limit Sequence (page 17) for an example.
For aggregation operations on *sharded collections* (page 18), this optimization reduces the results returned from each shard.

**$\text{redact} + \text{match} \text{ Sequence Optimization}**  
When possible, when the pipeline has the $\text{redact}$ stage immediately followed by the $\text{match}$ stage, the aggregation can sometimes add a portion of the $\text{match}$ stage before the $\text{redact}$ stage. If the added $\text{match}$ stage is at the start of a pipeline, the aggregation can use an index as well as query the collection to limit the number of documents that enter the pipeline. See *Pipeline Operators and Indexes* (page 9) for more information.

For example, if the pipeline consists of the following stages:

```
{ $redact: { $cond: { if: { $eq: [ "$level", 5 ] }, then: "$\text{PRUNE}$", else: "$\text{DESCEND}$" } } },
{ $match: { year: 2014, category: { $ne: "Z" } } }
```

The optimizer can add the same $\text{match}$ stage before the $\text{redact}$ stage:

```
{ $match: { year: 2014 } },
{ $redact: { $cond: { if: { $eq: [ "$level", 5 ] }, then: "$\text{PRUNE}$", else: "$\text{DESCEND}$" } } },
{ $match: { year: 2014, category: { $ne: "Z" } } }
```

**Pipeline Coalescence Optimization**

When possible, the optimization phase coalesces a pipeline stage into its predecessor. Generally, coalescence occurs *after* any sequence reordering optimization.

**$\text{sort} + \text{limit} \text{ Coalescence}**  
When a $\text{sort}$ immediately precedes a $\text{limit}$, the optimizer can coalesce the $\text{limit}$ into the $\text{sort}$. This allows the sort operation to only maintain the top $n$ results as it progresses, where $n$ is the specified limit, and MongoDB only needs to store $n$ items in memory. See *sort-and-memory* for more information.

**$\text{limit} + \text{limit} \text{ Coalescence}**  
When a $\text{limit}$ immediately follows another $\text{limit}$, the two stages can coalesce into a single $\text{limit}$ where the limit amount is the *smaller* of the two initial limit amounts. For example, a pipeline contains the following sequence:

```
{ $limit: 100 },
{ $limit: 10 }
```

Then the second $\text{limit}$ stage can coalesce into the first $\text{limit}$ stage and result in a single $\text{limit}$ stage where the limit amount 10 is the minimum of the two initial limits 100 and 10.

```
{ $limit: 10 }
```

**$\text{skip} + \text{skip} \text{ Coalescence}**  
When a $\text{skip}$ immediately follows another $\text{skip}$, the two stages can coalesce into a single $\text{skip}$ where the skip amount is the *sum* of the two initial skip amounts. For example, a pipeline contains the following sequence:

```
{ $skip: 5 },
{ $skip: 2 }
```

Then the second $\text{skip}$ stage can coalesce into the first $\text{skip}$ stage and result in a single $\text{skip}$ stage where the skip amount 7 is the sum of the two initial limits 5 and 2.

---

11 The optimization will still apply when allowDiskUse is true and the $n$ items exceed the aggregation memory limit (page 18).
$match + $match Coalescence  When a $match immediately follows another $match, the two stages can coalesce into a single $match combining the conditions with an $and. For example, a pipeline contains the following sequence:

```
{ $match: { year: 2014 } },
{ $match: { status: "A" } }
```

Then the second $match stage can coalesce into the first $match stage and result in a single $match stage

```
{ $match: { $and: [ { "year" : 2014 }, { "status" : "A" } ] } }
```

Examples

The following examples are some sequences that can take advantage of both sequence reordering and coalescence. Generally, coalescence occurs after any sequence reordering optimization.

$sort + $skip + $limit Sequence  A pipeline contains a sequence of $sort followed by a $skip followed by a $limit:

```
{ $sort: { age : -1 } },
{ $skip: 10 },
{ $limit: 5 }
```

First, the optimizer performs the $sort + $limit Sequence Optimization (page 15) to transforms the sequence to the following:

```
{ $sort: { age : -1 } },
{ $limit: 15 }
{ $skip: 10 }
```

The $sort + $limit Sequence Optimization (page 15) increases the $limit amount with the reordering. See $sort + $limit Sequence Optimization (page 15) for details.

The reordered sequence now has $sort immediately preceding the $limit, and the pipeline can coalesce the two stages to decrease memory usage during the sort operation. See $sort + $limit Coalescence (page 16) for more information.

$limit + $skip + $limit + $skip Sequence  A pipeline contains a sequence of alternating $limit and $skip stages:

```
{ $limit: 100 },
{ $skip: 5 },
{ $limit: 10 },
{ $skip: 2 }
```

The $skip + $limit Sequence Optimization (page 15) reverses the position of the { $skip: 5 } and { $limit: 10 } stages and increases the limit amount:

```
{ $limit: 100 },
{ $limit: 15},
{ $skip: 5 },
{ $skip: 2 }
```
The optimizer then coalesces the two $limit stages into a single $limit stage and the two $skip stages into a single $skip stage. The resulting sequence is the following:

{ $limit: 15 },
{ $skip: 7 }

See $limit + $limit Coalescence (page 16) and $skip + $skip Coalescence (page 16) for details.

explain option in the db.collection.aggregate()

Aggregation Pipeline Limits

Aggregation operations with the aggregate command have the following limitations.

Result Size Restrictions

If the aggregate command returns a single document that contains the complete result set, the command will produce an error if the result set exceeds the BSON Document Size limit, which is currently 16 megabytes. To manage result sets that exceed this limit, the aggregate command can return result sets of any size if the command return a cursor or store the results to a collection.

Changed in version 2.6: The aggregate command can return results as a cursor or store the results in a collection, which are not subject to the size limit. The db.collection.aggregate() returns a cursor and can return result sets of any size.

Memory Restrictions

Changed in version 2.6.

Pipeline stages have a limit of 100 megabytes of RAM. If a stage exceeds this limit, MongoDB will produce an error. To allow for the handling of large datasets, use the allowDiskUse option to enable aggregation pipeline stages to write data to temporary files.

See also:
sort-memory-limit and group-memory-limit.

Aggregation Pipeline and Sharded Collections

The aggregation pipeline supports operations on sharded collections. This section describes behaviors specific to the aggregation pipeline (page 9) and sharded collections.

Behavior

Changed in version 2.6.

When operating on a sharded collection, the aggregation pipeline is split into two parts. The first pipeline runs on each shard, or if an early $match can exclude shards through the use of the shard key in the predicate, the pipeline runs on only the relevant shards.
The second pipeline consists of the remaining pipeline stages and runs on the primary shard. The primary shard merges the cursors from the other shards and runs the second pipeline on these results. The primary shard forwards the final results to the mongos. In previous versions, the second pipeline would run on the mongos.\[12\]

**Optimization**

When splitting the aggregation pipeline into two parts, the pipeline is split to ensure that the shards perform as many stages as possible with consideration for optimization.

To see how the pipeline was split, include the explain option in the db.collection.aggregate() method. Optimizations are subject to change between releases.

**Map-Reduce and Sharded Collections**

Map-reduce supports operations on sharded collections, both as an input and as an output. This section describes the behaviors of mapReduce specific to sharded collections.

**Sharded Collection as Input**

When using sharded collection as the input for a map-reduce operation, mongos will automatically dispatch the map-reduce job to each shard in parallel. There is no special option required. mongos will wait for jobs on all shards to finish.

**Sharded Collection as Output**

Changed in version 2.2.

If the out field for mapReduce has the sharded value, MongoDB shards the output collection using the _id field as the shard key.

To output to a sharded collection:

- If the output collection does not exist, MongoDB creates and shards the collection on the _id field.
- For a new or an empty sharded collection, MongoDB uses the results of the first stage of the map-reduce operation to create the initial chunks distributed among the shards.
- mongos dispatches, in parallel, a map-reduce post-processing job to every shard that owns a chunk. During the post-processing, each shard will pull the results for its own chunks from the other shards, run the final reduce/finalize, and write locally to the output collection.

**Note:**

- During later map-reduce jobs, MongoDB splits chunks as needed.
- Balancing of chunks for the output collection is automatically prevented during post-processing to avoid concurrency issues.

In MongoDB 2.0:

- mongos retrieves the results from each shard, performs a merge sort to order the results, and proceeds to the reduce/finalize phase as needed. mongos then writes the result to the output collection in sharded mode.

\[12\] Until all shards upgrade to v2.6, the second pipeline runs on the mongos if any shards are still running v2.4.
• This model requires only a small amount of memory, even for large data sets.
• Shard chunks are not automatically split during insertion. This requires manual intervention until the chunks are granular and balanced.

**Important:** For best results, only use the sharded output options for `mapReduce` in version 2.2 or later.

**Map Reduce Concurrency**

The map-reduce operation is composed of many tasks, including reads from the input collection, executions of the `map` function, executions of the `reduce` function, writes to a temporary collection during processing, and writes to the output collection.

During the operation, map-reduce takes the following locks:

• The read phase takes a read lock. It yields every 100 documents.
• The insert into the temporary collection takes a write lock for a single write.
• If the output collection does not exist, the creation of the output collection takes a write lock.
• If the output collection exists, then the output actions (i.e. `merge`, `replace`, `reduce`) take a write lock. This write lock is **global**, and blocks all operations on the mongod instance.

Changed in version 2.4: The V8 JavaScript engine, which became the default in 2.4, allows multiple JavaScript operations to execute at the same time. Prior to 2.4, JavaScript code (i.e. `map`, `reduce`, `finalize` functions) executed in a single thread.

**Note:** The final write lock during post-processing makes the results appear atomically. However, output actions `merge` and `reduce` may take minutes to process. For the `merge` and `reduce`, the `nonAtomic` flag is available, which releases the lock between writing each output document. See the `db.collection.mapReduce()` reference for more information.

### 3 Aggregation Examples

This document provides the practical examples that display the capabilities of aggregation (page 7).

**Aggregation with the Zip Code Data Set** (page 21) Use the aggregation pipeline to group values and to calculate aggregated sums and averages for a collection of United States zip codes.

**Aggregation with User Preference Data** (page 24) Use the pipeline to sort, normalize, and sum data on a collection of user data.

**Map-Reduce Examples** (page 28) Define map-reduce operations that select ranges, group data, and calculate sums and averages.

**Perform Incremental Map-Reduce** (page 31) Run a map-reduce operations over one collection and output results to another collection.

**Troubleshoot the Map Function** (page 33) Steps to troubleshoot the map function.

**Troubleshoot the Reduce Function** (page 34) Steps to troubleshoot the reduce function.
3.1 Aggregation with the Zip Code Data Set

The examples in this document use the `zipcodes` collection. This collection is available at: media.mongodb.org/zips.json\(^1\). Use `mongoimport` to load this data set into your `mongod` instance.

Data Model

Each document in the `zipcodes` collection has the following form:

```json
{
  "_id": "10280",
  "city": "NEW YORK",
  "state": "NY",
  "pop": 5574,
  "loc": [
    -74.016323,
    40.710537
  ]
}
```

- The `_id` field holds the zip code as a string.
- The `city` field holds the city name. A city can have more than one zip code associated with it as different sections of the city can each have a different zip code.
- The `state` field holds the two letter state abbreviation.
- The `pop` field holds the population.
- The `loc` field holds the location as a latitude longitude pair.

aggregate() Method

All of the following examples use the `aggregate()` helper in the `mongo` shell.

The `aggregate()` method uses the aggregation pipeline (page 9) to processes documents into aggregated results. An aggregation pipeline (page 9) consists of stages with each stage processing the documents as they pass along the pipeline. Documents pass through the stages in sequence.

The `aggregate()` method in the `mongo` shell provides a wrapper around the `aggregate` database command. See the documentation for your driver for a more idiomatic interface for data aggregation operations.

Return States with Populations above 10 Million

The following aggregation operation returns all states with total population greater than 10 million:

```javascript
db.zipcodes.aggregate( [
  { $group: { _id: "$state", totalPop: { $sum: "$pop" } } },
  { $match: { totalPop: { $gte: 10*1000*1000 } } }
]
)
```

In this example, the aggregation pipeline (page 9) consists of the `$group` stage followed by the `$match` stage:

- The `$group` stage groups the documents of the `zipcode` collection by the `state` field, calculates the `totalPop` field for each state, and outputs a document for each unique state.

\(^1\)http://media.mongodb.org/zips.json

---

21
The new per-state documents have two fields: the _id field and the totalPop field. The _id field contains the value of the state; i.e. the group by field. The totalPop field is a calculated field that contains the total population of each state. To calculate the value, $group uses the $sum operator to add the population field (pop) for each state.

After the $group stage, the documents in the pipeline resemble the following:

```json
{  
  "_id" : "AK",
  "totalPop" : 550043
}
```

• The $match stage filters these grouped documents to output only those documents whose totalPop value is greater than or equal to 10 million. The $match stage does not alter the matching documents but outputs the matching documents unmodified.

The equivalent SQL for this aggregation operation is:

```sql
SELECT state, SUM(pop) AS totalPop
FROM zipcodes
GROUP BY state
HAVING totalPop >= (10*1000*1000)
```

See also: $group, $match, $sum

Return Average City Population by State

The following aggregation operation returns the average populations for cities in each state:

```javascript
db.zipcodes.aggregate( [  
  { $group: { _id: { state: "$state", city: "$city" }, pop: { $sum: "$pop" } } },  
  { $group: { _id: "$_id.state", avgCityPop: { $avg: "$pop" } } }  
] )
```

In this example, the aggregation pipeline (page 9) consists of the $group stage followed by another $group stage:

• The first $group stage groups the documents by the combination of city and state, uses the $sum expression to calculate the population for each combination, and outputs a document for each city and state combination. 14

After this stage in the pipeline, the documents resemble the following:

```json
{  
  "_id" : {  
    "state" : "CO",
    "city" : "EDGECATER"
  },
  "pop" : 13154
}
```

• A second $group stage groups the documents in the pipeline by the _id.state field (i.e. the state field inside the _id document), uses the $avg expression to calculate the average city population (avgCityPop) for each state, and outputs a document for each state.

The documents that result from this aggregation operation resembles the following:

14 A city can have more than one zip code associated with it as different sections of the city can each have a different zip code.
{ "_id" : "MN",
 "avgCityPop" : 5335
}

See also:
$group,$sum,$avg

Return Largest and Smallest Cities by State

The following aggregation operation returns the smallest and largest cities by population for each state:

db.zipcodes.aggregate( [

{ $group: 
   
   { _id: { state: "$state", city: "$city" },
   pop: { $sum: "$pop" } }
}
],

{ $sort: { pop: 1 } },

{ $group: 
   
   { _id: "$_id.state",
   biggestCity: { $last: "$_id.city" },
   biggestPop: { $last: "$pop" },
   smallestCity: { $first: "$_id.city" },
   smallestPop: { $first: "$pop" }
}
}

// the following $project is optional, and
// modifies the output format.

{ $project: 
   
   { _id: 0,
   state: "$_id",
   biggestCity: { name: "$biggestCity", pop: "$biggestPop" },
   smallestCity: { name: "$smallestCity", pop: "$smallestPop" }
}
]
}

In this example, the aggregation pipeline (page 9) consists of a $group stage, a $sort stage, another $group stage, and a $project stage:

- The first $group stage groups the documents by the combination of the city and state, calculates the sum of the pop values for each combination, and outputs a document for each city and state combination.

At this stage in the pipeline, the documents resemble the following:

{ "_id" : { "state" : "CO",
   "city" : "EDGEBWATER"
},
 "pop" : 13154
}
• The `$sort` stage orders the documents in the pipeline by the `pop` field value, from smallest to largest; i.e. by increasing order. This operation does not alter the documents.

• The next `$group` stage groups the now-sorted documents by the `_id.state` field (i.e. the `state` field inside the `_id` document) and outputs a document for each state.

The stage also calculates the following four fields for each state. Using the `$last` expression, the `$group` operator creates the `biggestCity` and `biggestPop` fields that store the city with the largest population and that population. Using the `$first` expression, the `$group` operator creates the `smallestCity` and `smallestPop` fields that store the city with the smallest population and that population.

The documents, at this stage in the pipeline, resemble the following:

```json
{
   "_id" : "WA",
   "biggestCity" : "SEATTLE",
   "biggestPop" : 520096,
   "smallestCity" : "BENGUE",
   "smallestPop" : 2
}
```

• The final `$project` stage renames the `_id` field to `state` and moves the `biggestCity`, `biggestPop`, `smallestCity`, and `smallestPop` into `biggestCity` and `smallestCity` embedded documents.

The output documents of this aggregation operation resemble the following:

```json
{
   "state" : "RI",
   "biggestCity" : {
      "name" : "CRANSTON",
      "pop" : 176404
   },
   "smallestCity" : {
      "name" : "CLAYVILLE",
      "pop" : 45
   }
}
```

### 3.2 Aggregation with User Preference Data

**Data Model**

Consider a hypothetical sports club with a database that contains a `users` collection that tracks the user’s join dates, sport preferences, and stores these data in documents that resemble the following:

```json
{
   _id : "jane",
   joined : ISODate("2011-03-02"),
   likes : ["golf", "racquetball"]
}
{
   _id : "joe",
   joined : ISODate("2012-07-02"),
   likes : ["tennis", "golf", "swimming"]
}
```
Normalize and Sort Documents

The following operation returns user names in upper case and in alphabetical order. The aggregation includes user names for all documents in the users collection. You might do this to normalize user names for processing.

```
db.users.aggregate(
  [
    { $project : { name:{$toUpper:$_id}, _id:0 } },
    { $sort : { name : 1 } }
  ]
)
```

All documents from the users collection pass through the pipeline, which consists of the following operations:

- The $project operator:
  - creates a new field called name.
  - converts the value of the _id to upper case, with the $toUpper operator. Then the $project creates a new field, named name to hold this value.
  - suppresses the id field. $project will pass the _id field by default, unless explicitly suppressed.
- The $sort operator orders the results by the name field.

The results of the aggregation would resemble the following:

```
{ "name" : "JANE" },
{ "name" : "JILL" },
{ "name" : "JOE" }
```

Return Usernames Ordered by Join Month

The following aggregation operation returns user names sorted by the month they joined. This kind of aggregation could help generate membership renewal notices.

```
db.users.aggregate(
  [
    { $project :
      { month_joined : { $month : "$joined" },
        name : "$_id",
        _id : 0
      }
    },
    { $sort : { month_joined : 1 } }
  ]
)
```

The pipeline passes all documents in the users collection through the following operations:

- The $project operator:
  - Creates two new fields: month_joined and name.
– Suppresses the id from the results. The aggregate() method includes the _id, unless explicitly suppressed.

• The $month operator converts the values of the joined field to integer representations of the month. Then the $project operator assigns those values to the month_joined field.

• The $sort operator sorts the results by the month_joined field.

The operation returns results that resemble the following:

```
{  
  "month_joined" : 1,
  "name" : "ruth"
},
{  
  "month_joined" : 1,
  "name" : "harold"
},
{  
  "month_joined" : 1,
  "name" : "kate"
}
{  
  "month_joined" : 2,
  "name" : "jill"
}
```

Return Total Number of Joins per Month

The following operation shows how many people joined each month of the year. You might use this aggregated data for recruiting and marketing strategies.

```
db.users.aggregate(
    [
        {
            "$project"
            : {
                "month_joined"
                : {
                    "$month"
                    : "joined"
                }
            },
        },
        {
            "$group"
            : {
                "_id"
                : {
                    "month_joined"
                    : "$month_joined"
                },
                "number"
                : {
                    "$sum"
                    : 1
                }
            },
        },
        {
            "$sort"
            : {
                "_id.month_joined"
                : 1
            }
        }
    ]
)
```

The pipeline passes all documents in the users collection through the following operations:

• The $project operator creates a new field called month_joined.

• The $month operator converts the values of the joined field to integer representations of the month. Then the $project operator assigns the values to the month_joined field.

• The $group operator collects all documents with a given month_joined value and counts how many documents there are for that value. Specifically, for each unique value, $group creates a new “per-month” document with two fields:
  - _id, which contains a nested document with the month_joined field and its value.
  - number, which is a generated field. The $sum operator increments this field by 1 for every document containing the given month_joined value.

• The $sort operator sorts the documents created by $group according to the contents of the month_joined field.

The result of this aggregation operation would resemble the following:
Return the Five Most Common “Likes”

The following aggregation collects top five most “liked” activities in the data set. This type of analysis could help inform planning and future development.

db.users.aggregate(
[  
  { $unwind : "$likes" },
  { $group : { _id : "$likes" , number : { $sum : 1 } } },
  { $sort : { number : -1 } },
  { $limit : 5 }
]
)

The pipeline begins with all documents in the users collection, and passes these documents through the following operations:

- The $unwind operator separates each value in the likes array, and creates a new version of the source document for every element in the array.

Example

Given the following document from the users collection:

```
{  
  _id : "jane",
  joined : ISODate("2011-03-02"),
  likes : ["golf", "racquetball"]
}
```

The $unwind operator would create the following documents:

```
{  
  _id : "jane",
  joined : ISODate("2011-03-02"),
  likes : "golf"
}
{  
  _id : "jane",
```
joined: ISODate("2011-03-02"),
likes: "racquetball"
}

- The $group operator collects all documents the same value for the likes field and counts each grouping. With this information, $group creates a new document with two fields:
  - _id, which contains the likes value.
  - number, which is a generated field. The $sum operator increments this field by 1 for every document containing the given likes value.
- The $sort operator sorts these documents by the number field in reverse order.
- The $limit operator only includes the first 5 result documents.

The results of aggregation would resemble the following:

```
{
   "_id": "golf",
   "number": 33
},
{
   "_id": "racquetball",
   "number": 31
},
{
   "_id": "swimming",
   "number": 24
},
{
   "_id": "handball",
   "number": 19
},
{
   "_id": "tennis",
   "number": 18
}
```

### 3.3 Map-Reduce Examples

In the mongo shell, the db.collection.mapReduce() method is a wrapper around the mapReduce command. The following examples use the db.collection.mapReduce() method:

Consider the following map-reduce operations on a collection orders that contains documents of the following prototype:

```
{   _id: ObjectId("50a8240b927d5d8b5891743c"),
    cust_id: "abc123",
    ord_date: new Date("Oct 04, 2012"),
    status: "A",
    price: 25,
    items: [ { sku: "mmm", qty: 5, price: 2.5 },
             { sku: "nnn", qty: 5, price: 2.5 } ]
}
Return the Total Price Per Customer

Perform the map-reduce operation on the orders collection to group by the cust_id, and calculate the sum of the price for each cust_id:

1. Define the map function to process each input document:
   - In the function, this refers to the document that the map-reduce operation is processing.
   - The function maps the price to the cust_id for each document and emits the cust_id and price pair.

   ```javascript
   var mapFunction1 = function() {
       emit(this.cust_id, this.price);
   };
   ```

2. Define the corresponding reduce function with two arguments keyCustId and valuesPrices:
   - The valuesPrices is an array whose elements are the price values emitted by the map function and grouped by keyCustId.
   - The function reduces the valuesPrice array to the sum of its elements.

   ```javascript
   var reduceFunction1 = function(keyCustId, valuesPrices) {
       return Array.sum(valuesPrices);
   };
   ```

3. Perform the map-reduce on all documents in the orders collection using the mapFunction1 map function and the reduceFunction1 reduce function.

   ```javascript
   db.orders.mapReduce(
       mapFunction1,
       reduceFunction1,
       { out: "map_reduce_example" }
   )
   ```

This operation outputs the results to a collection named map_reduce_example. If the map_reduce_example collection already exists, the operation will replace the contents with the results of this map-reduce operation.

Calculate Order and Total Quantity with Average Quantity Per Item

In this example, you will perform a map-reduce operation on the orders collection for all documents that have an ord_date value greater than 01/01/2012. The operation groups by the item.sku field, and calculates the number of orders and the total quantity ordered for each sku. The operation concludes by calculating the average quantity per order for each sku value:

1. Define the map function to process each input document:
   - In the function, this refers to the document that the map-reduce operation is processing.
   - For each item, the function associates the sku with a new object value that contains the count of 1 and the item qty for the order and emits the sku and value pair.

   ```javascript
   var mapFunction2 = function() {
       for (var idx = 0; idx < this.items.length; idx++) {
           var key = this.items[idx].sku;
           var value = {
               count: 1,
               qty: this.items[idx].qty
           }
           emit(key, value);
       }
   };
   ```
2. Define the corresponding reduce function with two arguments `keySKU` and `countObjVals`:

- `countObjVals` is an array whose elements are the objects mapped to the grouped `keySKU` values passed by map function to the reducer function.
- The function reduces the `countObjVals` array to a single object `reducedValue` that contains the `count` and the `qty` fields.
- In `reducedVal`, the `count` field contains the sum of the `count` fields from the individual array elements, and the `qty` field contains the sum of the `qty` fields from the individual array elements.

```javascript
var reduceFunction2 = function (keySKU, countObjVals) {
  reducedVal = { count: 0, qty: 0 };
  for (var idx = 0; idx < countObjVals.length; idx++) {
    reducedVal.count += countObjVals[idx].count;
    reducedVal.qty += countObjVals[idx].qty;
  }
  return reducedVal;
};
```

3. Define a finalize function with two arguments `key` and `reducedVal`. The function modifies the `reducedVal` object to add a computed field named `avg` and returns the modified object:

```javascript
var finalizeFunction2 = function (key, reducedVal) {
  reducedVal.avg = reducedVal.qty/reducedVal.count;
  return reducedVal;
};
```

4. Perform the map-reduce operation on the `orders` collection using the `mapFunction2`, `reduceFunction2`, and `finalizeFunction2` functions.

```javascript
db.orders.mapReduce( mapFunction2, 
  reduceFunction2, 
  {
    out: { merge: "map_reduce_example" },
    query: { ord_date: 
      { $gt: new Date('01/01/2012') } 
    },
    finalize: finalizeFunction2
  }
)
```

This operation uses the `query` field to select only those documents with `ord_date` greater than `new Date(01/01/2012)`. Then it output the results to a collection `map_reduce_example`. If the `map_reduce_example` collection already exists, the operation will merge the existing contents with the results of this map-reduce operation.
3.4 Perform Incremental Map-Reduce

Map-reduce operations can handle complex aggregation tasks. To perform map-reduce operations, MongoDB provides the `mapReduce` command and, in the `mongo` shell, the `db.collection.mapReduce()` wrapper method.

If the map-reduce data set is constantly growing, you may want to perform an incremental map-reduce rather than performing the map-reduce operation over the entire data set each time.

To perform incremental map-reduce:

1. Run a map-reduce job over the current collection and output the result to a separate collection.
2. When you have more data to process, run subsequent map-reduce job with:
   - the `query` parameter that specifies conditions that match only the new documents.
   - the `out` parameter that specifies the `reduce` action to merge the new results into the existing output collection.

Consider the following example where you schedule a map-reduce operation on a `sessions` collection to run at the end of each day.

**Data Setup**

The `sessions` collection contains documents that log users’ sessions each day, for example:

```javascript
db.sessions.save( { userid: "a", ts: ISODate('2011-11-03 14:17:00'), length: 95 } );
db.sessions.save( { userid: "b", ts: ISODate('2011-11-03 14:23:00'), length: 110 } );
db.sessions.save( { userid: "c", ts: ISODate('2011-11-03 15:02:00'), length: 120 } );
db.sessions.save( { userid: "d", ts: ISODate('2011-11-03 16:45:00'), length: 45 } );
db.sessions.save( { userid: "a", ts: ISODate('2011-11-04 11:05:00'), length: 105 } );
db.sessions.save( { userid: "b", ts: ISODate('2011-11-04 13:14:00'), length: 120 } );
db.sessions.save( { userid: "c", ts: ISODate('2011-11-04 17:00:00'), length: 130 } );
db.sessions.save( { userid: "d", ts: ISODate('2011-11-04 15:37:00'), length: 65 } );
```

**Initial Map-Reduce of Current Collection**

Run the first map-reduce operation as follows:

1. Define the map function that maps the `userid` to an object that contains the fields `userid`, `total_time`, `count`, and `avg_time`:

   ```javascript
   var mapFunction = function() {
       var key = this.userid;
       var value = {
           userid: this.userid,
           total_time: this.length,
           count: 1,
           avg_time: 0
       };

       emit( key, value );
   };
   ```

2. Define the corresponding reduce function with two arguments `key` and `values` to calculate the total time and the count. The `key` corresponds to the `userid`, and the `values` is an array whose elements corresponds to the individual objects mapped to the `userid` in the `mapFunction`.

   ```javascript
   var reduceFunction = function(key, values) {
       var total_time = 0;
       var count = 0;
       for (var i = 0; i < values.length; i++) {
           total_time += values[i].total_time;
           count += values[i].count;
       }
       return { userid: key, total_time: total_time, count: count, avg_time: total_time / count };
   };
   ```

   ```javascript
   db.sessions.mapReduce( { collection: "sessions" }, { map: mapFunction, reduce: reduceFunction }, { out: "results" } );
   ```
```javascript
var reduceFunction = function(key, values) {
    var reducedObject = {
        userid: key,
        total_time: 0,
        count: 0,
        avg_time: 0
    }
    values.forEach(
        function (value) {
            reducedObject.total_time += value.total_time;
            reducedObject.count += value.count;
        }
    );
    return reducedObject;
};

3. Define the finalize function with two arguments key and reducedValue. The function modifies the reducedValue document to add another field average and returns the modified document.

var finalizeFunction = function (key, reducedValue) {
    if (reducedValue.count > 0)
        reducedValue.avg_time = reducedValue.total_time / reducedValue.count;
    return reducedValue;
};

4. Perform map-reduce on the session collection using the mapFunction, the reduceFunction, and the finalizeFunction functions. Output the results to a collection session_stat. If the session_stat collection already exists, the operation will replace the contents:

db.sessions.mapReduce(mapFunction,
    reduceFunction,
    {
        out: "session_stat",
        finalize: finalizeFunction
    }
)

Subsequent Incremental Map-Reduce

Later, as the sessions collection grows, you can run additional map-reduce operations. For example, add new documents to the sessions collection:

db.sessions.save({ userid: "a", ts: ISODate('2011-11-05 14:17:00'), length: 100 });
db.sessions.save({ userid: "b", ts: ISODate('2011-11-05 14:23:00'), length: 115 });
db.sessions.save({ userid: "c", ts: ISODate('2011-11-05 15:02:00'), length: 125 });
db.sessions.save({ userid: "d", ts: ISODate('2011-11-05 16:45:00'), length: 55 });

At the end of the day, perform incremental map-reduce on the sessions collection, but use the query field to select only the new documents. Output the results to the collection session_stat, but reduce the contents with the results of the incremental map-reduce:

db.sessions.mapReduce(mapFunction,
    reduceFunction,
    {
```
3.5 Troubleshoot the Map Function

The map function is a JavaScript function that associates or “maps” a value with a key and emits the key and value pair during a map-reduce (page 10) operation.

To verify the key and value pairs emitted by the map function, write your own emit function.

Consider a collection orders that contains documents of the following prototype:

```javascript
{  
  _id: ObjectId("50a8240b927d5d8b5891743c"),  
  cust_id: "abc123",  
  ord_date: new Date("Oct 04, 2012"),  
  status: "A",  
  price: 250,  
  items: [  
    { sku: "mmm", qty: 5, price: 2.5 },  
    { sku: "nnn", qty: 5, price: 2.5 }  
  ]
}
```

1. Define the map function that maps the price to the cust_id for each document and emits the cust_id and price pair:

   ```javascript
   var map = function() {  
     emit(this.cust_id, this.price);  
   };
   ```

2. Define the emit function to print the key and value:

   ```javascript
   var emit = function(key, value) {  
     print("emit");  
     print("key: " + key + " value: " + tojson(value));  
   };
   ```

3. Invoke the map function with a single document from the orders collection:

   ```javascript
   var myDoc = db.orders.findOne( { _id: ObjectId("50a8240b927d5d8b5891743c") } );
   map.apply(myDoc);
   ```

4. Verify the key and value pair is as you expected.

   ```javascript
   emit
   key: abc123 value:250
   ```

5. Invoke the map function with multiple documents from the orders collection:

   ```javascript
   var myCursor = db.orders.find( { cust_id: "abc123" } );
   ```

   ```javascript
   while (myCursor.hasNext()) {  
     var doc = myCursor.next();  
     print ("document _id= " + tojson(doc._id));  
     map.apply(doc);  
     print();  
   }
   ```
6. Verify the key and value pairs are as you expected.

See also:

The map function must meet various requirements. For a list of all the requirements for the map function, see mapReduce, or the mongo shell helper method db.collection.mapReduce().

### 3.6 Troubleshoot the Reduce Function

The reduce function is a JavaScript function that “reduces” to a single object all the values associated with a particular key during a map-reduce (page 10) operation. The reduce function must meet various requirements. This tutorial helps verify that the reduce function meets the following criteria:

- The reduce function must return an object whose type must be **identical** to the type of the value emitted by the map function.
- The order of the elements in the valuesArray should not affect the output of the reduce function.
- The reduce function must be **idempotent**.

For a list of all the requirements for the reduce function, see mapReduce, or the mongo shell helper method db.collection.mapReduce().

#### Confirm Output Type

You can test that the reduce function returns a value that is the same type as the value emitted from the map function.

1. Define a reduceFunction1 function that takes the arguments keyCustId and valuesPrices. valuesPrices is an array of integers:

   ```javascript
   var reduceFunction1 = function(keyCustId, valuesPrices) {
       return Array.sum(valuesPrices);
   };
   ```

2. Define a sample array of integers:

   ```javascript
   var myTestValues = [5, 5, 10];
   ```

3. Invoke the reduceFunction1 with myTestValues:

   ```javascript
   reduceFunction1('myKey', myTestValues);
   ```

4. Verify the reduceFunction1 returned an integer:

   20

5. Define a reduceFunction2 function that takes the arguments keySKU and valuesCountObjects. valuesCountObjects is an array of documents that contain two fields count and qty:

   ```javascript
   var reduceFunction2 = function(keySKU, valuesCountObjects) {
       reducedValue = { count: 0, qty: 0 };

       for (var idex = 0; idex < valuesCountObjects.length; idex++) {
           reducedValue.count += valuesCountObjects[idex].count;
           reducedValue.qty += valuesCountObjects[idex].qty;
       }

       return reducedValue;
   };
   ```
6. Define a sample array of documents:

```javascript
var myTestObjects = [
    { count: 1, qty: 5 },
    { count: 2, qty: 10 },
    { count: 3, qty: 15 }
];
```

7. Invoke the `reduceFunction2` with `myTestObjects`:

```javascript
reduceFunction2('myKey', myTestObjects);
```

8. Verify the `reduceFunction2` returned a document with exactly the `count` and the `qty` field:

```javascript
{ "count" : 6, "qty" : 30 }
```

### Ensure Insensitivity to the Order of Mapped Values

The `reduce` function takes a `key` and a `values` array as its argument. You can test that the result of the `reduce` function does not depend on the order of the elements in the `values` array.

1. Define a sample `values1` array and a sample `values2` array that only differ in the order of the array elements:

```javascript
var values1 = [
    { count: 1, qty: 5 },
    { count: 2, qty: 10 },
    { count: 3, qty: 15 }
];

var values2 = [
    { count: 3, qty: 15 },
    { count: 1, qty: 5 },
    { count: 2, qty: 10 }
];
```

2. Define a `reduceFunction2` function that takes the arguments `keySKU` and `valuesCountObjects`. `valuesCountObjects` is an array of documents that contain two fields `count` and `qty`:

```javascript
var reduceFunction2 = function(keySKU, valuesCountObjects) {
    reducedValue = { count: 0, qty: 0 };
    for (var idx = 0; idx < valuesCountObjects.length; idx++) {
        reducedValue.count += valuesCountObjects[idx].count;
        reducedValue.qty += valuesCountObjects[idx].qty;
    }
    return reducedValue;
};
```

3. Invoke the `reduceFunction2` first with `values1` and then with `values2`:

```javascript
reduceFunction2('myKey', values1);
reduceFunction2('myKey', values2);
```

4. Verify the `reduceFunction2` returned the same result:

```javascript
{ "count" : 6, "qty" : 30 }
```
Ensure Reduce Function Idempotence

Because the map-reduce operation may call a reduce multiple times for the same key, and won’t call a reduce for single instances of a key in the working set, the reduce function must return a value of the same type as the value emitted from the map function. You can test that the reduce function process “reduced” values without affecting the final value.

1. Define a reduceFunction2 function that takes the arguments keySKU and valuesCountObjects. valuesCountObjects is an array of documents that contain two fields count and qty:

   ```javascript
   var reduceFunction2 = function(keySKU, valuesCountObjects) {
     reducedValue = { count: 0, qty: 0 };  
     for (var idx = 0; idx < valuesCountObjects.length; idx++) {
       reducedValue.count += valuesCountObjects[idx].count;  
       reducedValue.qty += valuesCountObjects[idx].qty;  
     }  
     return reducedValue;  
   };
   ```

2. Define a sample key:

   ```javascript
   var myKey = 'myKey';
   ```

3. Define a sample valuesIdempotent array that contains an element that is a call to the reduceFunction2 function:

   ```javascript
   var valuesIdempotent = [
     { count: 1, qty: 5 },
     { count: 2, qty: 10 },
     reduceFunction2(myKey, [ { count:3, qty: 15 } ])
   ];
   ```

4. Define a sample values1 array that combines the values passed to reduceFunction2:

   ```javascript
   var values1 = [
     { count: 1, qty: 5 },
     { count: 2, qty: 10 },
     { count: 3, qty: 15 }
   ];
   ```

5. Invoke the reduceFunction2 first with myKey and valuesIdempotent and then with myKey and values1:

   ```javascript
   reduceFunction2(myKey, valuesIdempotent);
   reduceFunction2(myKey, values1);
   ```

6. Verify the reduceFunction2 returned the same result:

   ```javascript
   { "count" : 6, "qty" : 30 }
   ```

Aggregation Commands (page 46) The reference for the data aggregation commands, which provide the interfaces to MongoDB’s aggregation capability.

Variables in Aggregation Expressions (page 46) Use of variables in aggregation pipeline expressions.

4.1 Aggregation Pipeline Quick Reference

Stages

Pipeline stages appear in an array. Documents pass through the stages in sequence. All except the $out and $geoNear stages can appear multiple times in a pipeline.

db.collection.aggregate([ { <stage> }, ... ])

---

17https://www.mongodb.com/presentations/aggregation-framework-0?jmp=docs
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$project</td>
<td>Reshapes each document in the stream, such as by adding new fields or removing existing fields. For each input document, outputs one document.</td>
</tr>
<tr>
<td>$match</td>
<td>Filters the document stream to allow only matching documents to pass unmodified into the next pipeline stage. $match uses standard MongoDB queries. For each input document, outputs either one document (a match) or zero documents (no match).</td>
</tr>
<tr>
<td>$redact</td>
<td>Reshapes each document in the stream by restricting the content for each document based on information stored in the documents themselves. Incorporates the functionality of $project and $match. Can be used to implement field level redaction. For each input document, outputs either one or zero document.</td>
</tr>
<tr>
<td>$limit</td>
<td>Passes the first $n$ documents unmodified to the pipeline where $n$ is the specified limit. For each input document, outputs either one document (for the first $n$ documents) or zero documents (after the first $n$ documents).</td>
</tr>
<tr>
<td>$skip</td>
<td>Skips the first $n$ documents where $n$ is the specified skip number and passes the remaining documents unmodified to the pipeline. For each input document, outputs either zero documents (for the first $n$ documents) or one document (if after the first $n$ documents).</td>
</tr>
<tr>
<td>$unwind</td>
<td>Deconstructs an array field from the input documents to output a document for each element. Each output document replaces the array with an element value. For each input document, outputs $n$ documents where $n$ is the number of array elements and can be zero for an empty array.</td>
</tr>
<tr>
<td>$group</td>
<td>Groups input documents by a specified identifier expression and applies the accumulator expression(s), if specified, to each group. Consumes all input documents and outputs one document per each distinct group. The output documents only contain the identifier field and, if specified, accumulated fields.</td>
</tr>
<tr>
<td>$sort</td>
<td>Reorders the document stream by a specified sort key. Only the order changes; the documents remain unmodified. For each input document, outputs one document.</td>
</tr>
<tr>
<td>$geoNear</td>
<td>Returns an ordered stream of documents based on the proximity to a geospatial point. Incorporates the functionality of $match, $sort, and $limit for geospatial data. The output documents include an additional distance field and can include a location identifier field.</td>
</tr>
<tr>
<td>$out</td>
<td>Writes the resulting documents of the aggregation pipeline to a collection. To use the $out stage, it must be the last stage in the pipeline.</td>
</tr>
</tbody>
</table>

**Expressions**

Expressions can include field paths and system variables (page 38), literals (page 39), expression objects (page 39), and expression operators (page 39). Expressions can be nested.

**Field Path and System Variables**

Aggregation expressions use field path to access fields in the input documents. To specify a field path, use a string that prefixes with a dollar sign $ the field name or the dotted field name, if the field is in embedded document. For example, "$user" to specify the field path for the user field or "$user.name" to specify the field path to "user.name" field.

"$<field>" is equivalent to "$$CURRENT.<field>" where the CURRENT (page 47) is a system variable that defaults to the root of the current object in the most stages, unless stated otherwise in specific stages. CURRENT (page 47) can be rebound.

Along with the CURRENT (page 47) system variable, other system variables (page 46) are also available for use in expressions. To use user-defined variables, use $let and $map expressions. To access variables in expressions, use a string that prefixes the variable name with $$.
Literals

Literals can be of any type. However, MongoDB parses string literals that start with a dollar sign $ as a path to a field and numeric/boolean literals in expression objects (page 39) as projection flags. To avoid parsing literals, use the $literal expression.

Expression Objects

Expression objects have the following form:

{ <field1>: <expression1>, ... }

If the expressions are numeric or boolean literals, MongoDB treats the literals as projection flags (e.g. 1 or true to include the field), valid only in the $project stage. To avoid treating numeric or boolean literals as projection flags, use the $literal expression to wrap the numeric or boolean literals.

Operator Expressions

Operator expressions are similar to functions that take arguments. In general, these expressions take an array of arguments and have the following form:

{ <operator>: [ <argument1>, <argument2> ... ] }

If operator accepts a single argument, you can omit the outer array designating the argument list:

{ <operator>: <argument> }

To avoid parsing ambiguity if the argument is a literal array, you must wrap the literal array in a $literal expression or keep the outer array that designates the argument list.

Boolean Expressions

Boolean expressions evaluate their argument expressions as booleans and return a boolean as the result.

In addition to the false boolean value, Boolean expression evaluates as false the following: null, 0, and undefined values. The Boolean expression evaluates all other values as true, including non-zero numeric values and arrays.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$and</td>
<td>Returns true only when all its expressions evaluate to true. Accepts any number of argument expressions.</td>
</tr>
<tr>
<td>$or</td>
<td>Returns true when any of its expressions evaluates to true. Accepts any number of argument expressions.</td>
</tr>
<tr>
<td>$not</td>
<td>Returns the boolean value that is the opposite of its argument expression. Accepts a single argument expression.</td>
</tr>
</tbody>
</table>

Set Expressions

Set expressions performs set operation on arrays, treating arrays as sets. Set expressions ignores the duplicate entries in each input array and the order of the elements.

If the set operation returns a set, the operation filters out duplicates in the result to output an array that contains only unique entries. The order of the elements in the output array is unspecified.

If a set contains a nested array element, the set expression does not descend into the nested array but evaluates the array at top-level.
Comparison Expressions

Comparison expressions return a boolean except for $\text{cmp}$ which returns a number.

The comparison expressions take two argument expressions and compare both value and type, using the specified BSON comparison order for values of different types.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{cmp}$</td>
<td>Returns: 0 if the two values are equivalent, 1 if the first value is greater than the second, and -1 if the first value is less than the second.</td>
</tr>
<tr>
<td>$\text{eq}$</td>
<td>Returns true if the values are equivalent.</td>
</tr>
<tr>
<td>$\text{gt}$</td>
<td>Returns true if the first value is greater than the second.</td>
</tr>
<tr>
<td>$\text{gte}$</td>
<td>Returns true if the first value is greater than or equal to the second.</td>
</tr>
<tr>
<td>$\text{lt}$</td>
<td>Returns true if the first value is less than the second.</td>
</tr>
<tr>
<td>$\text{lte}$</td>
<td>Returns true if the first value is less than or equal to the second.</td>
</tr>
<tr>
<td>$\text{ne}$</td>
<td>Returns true if the values are not equivalent.</td>
</tr>
</tbody>
</table>

Arithmetic Expressions

Arithmetic expressions perform mathematic operations on numbers. Some arithmetic expressions can also support date arithmetic.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{add}$</td>
<td>Adds numbers to return the sum, or adds numbers and a date to return a new date. If adding numbers and a date, treats the numbers as milliseconds. Accepts any number of argument expressions, but at most, one expression can resolve to a date.</td>
</tr>
<tr>
<td>$\text{subtract}$</td>
<td>Returns the result of subtracting the second value from the first. If the two values are numbers, return the difference. If the two values are dates, return the difference in milliseconds. If the two values are a date and a number in milliseconds, return the resulting date. Accepts two argument expressions. If the two values are a date and a number, specify the date argument first as it is not meaningful to subtract a date from a number.</td>
</tr>
<tr>
<td>$\text{multiply}$</td>
<td>Multiplies numbers to return the product. Accepts any number of argument expressions.</td>
</tr>
<tr>
<td>$\text{divide}$</td>
<td>Returns the result of dividing the first number by the second. Accepts two argument expressions.</td>
</tr>
<tr>
<td>$\text{mod}$</td>
<td>Returns the remainder of the first number divided by the second. Accepts two argument expressions.</td>
</tr>
</tbody>
</table>

String Expressions

String expressions, with the exception of $\text{concat}$, only have a well-defined behavior for strings of ASCII characters.

$\text{concat}$ behavior is well-defined regardless of the characters used.

20[^1]

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$concat</td>
<td>Concatenates any number of strings.</td>
</tr>
<tr>
<td>$substr</td>
<td>Returns a substring of a string, starting at a specified index position up to a specified length. Accepts three expressions as arguments: the first argument must resolve to a string, and the second and third arguments must resolve to integers.</td>
</tr>
<tr>
<td>$toLowerCase</td>
<td>Converts a string to lowercase. Accepts a single argument expression.</td>
</tr>
<tr>
<td>$toUpperCase</td>
<td>Converts a string to uppercase. Accepts a single argument expression.</td>
</tr>
<tr>
<td>$strCases</td>
<td>Performs case-insensitive string comparison and returns: 0 if two strings are equivalent, 1 if the first string is greater than the second, and -1 if the first string is less than the second.</td>
</tr>
</tbody>
</table>

<td>Returns the milliseconds of a date as a number between 0 and 999.</td>
</tr>
<tr>
<td>$dateToString</td>
<td></td>
<td>Returns the date as a formatted string.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Conditional Expressions</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$cond</td>
<td></td>
<td>A ternary operator that evaluates one expression, and depending on the result, returns the value of the other two expressions. Accepts either three expressions in an ordered list or three named parameters.</td>
</tr>
<tr>
<td>$ifNull</td>
<td></td>
<td>Returns either the non-null result of the first expression or the result of the second expression if the first expression results in a null result. Null result encompasses instances of undefined values or missing fields. Accepts two expressions as arguments. The result of the second expression can be null.</td>
</tr>
</tbody>
</table>
Accumulators

Accumulators, available only for the $group stage, compute values by combining documents that share the same group key. Accumulators take as input a single expression, evaluating the expression once for each input document, and maintain their state for the group of documents.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$sum</td>
<td>Returns a sum for each group. Ignores non-numeric values.</td>
</tr>
<tr>
<td>$avg</td>
<td>Returns an average for each group. Ignores non-numeric values.</td>
</tr>
<tr>
<td>$first</td>
<td>Returns a value from the first document for each group. Order is only defined if the documents are in a defined order.</td>
</tr>
<tr>
<td>$last</td>
<td>Returns a value from the last document for each group. Order is only defined if the documents are in a defined order.</td>
</tr>
<tr>
<td>$max</td>
<td>Returns the highest expression value for each group.</td>
</tr>
<tr>
<td>$min</td>
<td>Returns the lowest expression value for each group.</td>
</tr>
<tr>
<td>$push</td>
<td>Returns an array of expression values for each group.</td>
</tr>
<tr>
<td>$addToSet</td>
<td>Returns an array of unique expression values for each group. Order of the array elements is undefined.</td>
</tr>
</tbody>
</table>

4.2 Aggregation Commands Comparison

The following table provides a brief overview of the features of the MongoDB aggregation commands.
<table>
<thead>
<tr>
<th>Description</th>
<th>aggregate</th>
<th>mapReduce</th>
<th>group</th>
</tr>
</thead>
<tbody>
<tr>
<td>New in version 2.2.</td>
<td>Designed with specific goals of improving performance and usability for aggregation tasks. Uses a “pipeline” approach where objects are transformed as they pass through a series of pipeline operators such as $group, $match, and $sort. See <a href="http://docs.mongodb.org/manual/reference/operator/aggregation">http://docs.mongodb.org/manual/reference/operator/aggregation</a> for more information on the pipeline operators.</td>
<td>Implements the Map-Reduce aggregation for processing large data sets.</td>
<td>Provides grouping functionality. Is slower than the aggregate command and has less functionality than the mapReduce command.</td>
</tr>
<tr>
<td>Key Features</td>
<td>Pipeline operators can be repeated as needed.</td>
<td>In addition to grouping operations, can perform complex aggregation tasks as well as perform incremental aggregation on continuously growing datasets. See Map-Reduce Examples (page 28) and Perform Incremental Map-Reduce (page 31).</td>
<td>Can either group by existing fields or with a custom keyf JavaScript function, can group by calculated fields. See group for information and example using the keyf function.</td>
</tr>
<tr>
<td></td>
<td>Pipeline operators need not produce one output document for every input document. Can also generate new documents or filter out documents.</td>
<td></td>
<td>Custom reduce and finalize JavaScript functions offer flexibility to grouping logic. See group for details and restrictions on these functions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Flexibility</td>
<td>Limited to the operators and expressions supported by the aggregation pipeline. However, can add computed fields, create new virtual sub-objects, and extract sub-fields into the top-level of results by using the $project pipeline operator. See $project for more information as well as <a href="http://docs.mongodb.org/manual/reference/operator/aggregation">http://docs.mongodb.org/manual/reference/operator/aggregation</a> for more information on all the available pipeline operators.</td>
<td>Returns results inline as an array of grouped items. The result set must fit within the maximum BSON document size limit. Changed in version 2.2: The returned array can contain at most 20,000 elements; i.e. at most 20,000 unique groupings. Previous versions had a limit of 10,000 elements.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Returns results in various options (inline, new collection, merge, replace, reduce). See mapReduce for details on the output options. Changed in version 2.2: Provides much better support for sharded map-reduce output than previous versions.</td>
<td>Does not support sharded collection. Prior to 2.4, JavaScript code executed in a single thread. See group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Supports non-sharded and sharded input collections.</td>
<td></td>
</tr>
<tr>
<td>Output Results</td>
<td>Returns results in various options (inline as a document that contains the result set, a cursor to the result set) or stores the results in a collection. The result is subject to the BSON Document size limit if returned inline as a document that contains the result set. Changed in version 2.6: Can return results as a cursor or store the results to a collection.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sharding Notes</td>
<td>Supports non-sharded and sharded input collections.</td>
<td>Supports non-sharded and sharded input collections.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Prior to 2.4, JavaScript code executed in a single thread. See Map-Reduce (page 10) and mapReduce</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>More Information</td>
<td>See Aggregation Pipeline (page 7) and aggregate</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
4.3 SQL to Aggregation Mapping Chart

The *aggregation pipeline* (page 7) allows MongoDB to provide native aggregation capabilities that corresponds to many common data aggregation operations in SQL.

The following table provides an overview of common SQL aggregation terms, functions, and concepts and the corresponding MongoDB aggregation operators:

<table>
<thead>
<tr>
<th>SQL Terms, Functions, and Concepts</th>
<th>MongoDB Aggregation Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>WHERE</td>
<td>$match</td>
</tr>
<tr>
<td>GROUP BY</td>
<td>$group</td>
</tr>
<tr>
<td>HAVING</td>
<td>$match</td>
</tr>
<tr>
<td>SELECT</td>
<td>$project</td>
</tr>
<tr>
<td>ORDER BY</td>
<td>$sort</td>
</tr>
<tr>
<td>LIMIT</td>
<td>$limit</td>
</tr>
<tr>
<td>SUM()</td>
<td>$sum</td>
</tr>
<tr>
<td>COUNT()</td>
<td>$sum</td>
</tr>
<tr>
<td>join</td>
<td>No direct corresponding operator; however, the $unwind operator allows for somewhat similar functionality, but with fields embedded within the document.</td>
</tr>
</tbody>
</table>

**Examples**

The following table presents a quick reference of SQL aggregation statements and the corresponding MongoDB statements. The examples in the table assume the following conditions:

- The SQL examples assume *two* tables, *orders* and *order_lineitem* that join by the *order_lineitem.order_id* and the *orders.id* columns.
- The MongoDB examples assume *one* collection *orders* that contain documents of the following prototype:

```javascript
{
  cust_id: "abc123",
  ord_date: ISODate("2012-11-02T17:04:11.102Z"),
  status: 'A',
  price: 50,
  items: [ { sku: "xxx", qty: 25, price: 1 },
    { sku: "yyy", qty: 25, price: 1 } ]
}
```
<table>
<thead>
<tr>
<th>SQL Example</th>
<th>MongoDB Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT COUNT(*) AS count FROM orders</code></td>
<td><code>db.orders.aggregate( [</code></td>
<td>Count all records from orders</td>
</tr>
<tr>
<td></td>
<td><code>{ _id: null, count: { $sum: 1 } }</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>] )</code></td>
<td></td>
</tr>
<tr>
<td><code>SELECT SUM(price) AS total FROM orders</code></td>
<td><code>db.orders.aggregate( [</code></td>
<td>Sum the price field from orders</td>
</tr>
<tr>
<td></td>
<td><code>{ _id: null, total: { $sum: &quot;$price&quot; } }</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>] )</code></td>
<td></td>
</tr>
<tr>
<td><code>SELECT cust_id, SUM(price) AS total FROM orders GROUP BY cust_id</code></td>
<td><code>db.orders.aggregate( [</code></td>
<td>For each unique cust_id, sum the price field.</td>
</tr>
<tr>
<td></td>
<td><code>{ _id: &quot;$cust_id&quot;, total: { $sum: &quot;$price&quot; } }</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>] )</code></td>
<td></td>
</tr>
<tr>
<td><code>SELECT cust_id, SUM(price) AS total FROM orders GROUP BY cust_id ORDER BY total</code></td>
<td><code>db.orders.aggregate( [</code></td>
<td>For each unique cust_id, sum the price field, results sorted by sum.</td>
</tr>
<tr>
<td></td>
<td><code>{ _sort: { total: 1 } }</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>] )</code></td>
<td></td>
</tr>
<tr>
<td><code>SELECT cust_id, ord_date, SUM(price) AS total FROM orders GROUP BY cust_id, ord_date</code></td>
<td><code>db.orders.aggregate( [</code></td>
<td>For each unique cust_id, ord_date grouping, sum the price field. Excludes the time portion of the date.</td>
</tr>
<tr>
<td></td>
<td><code>{ _id: { cust_id: &quot;$cust_id&quot;, ord_date: { month: { $month: &quot;$ord_date&quot; }, day: { $dayOfMonth: &quot;$ord_date&quot; }, year: { $year: &quot;$ord_date&quot; } }, total: { $sum: &quot;$price&quot; } } }</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>] )</code></td>
<td></td>
</tr>
<tr>
<td><code>SELECT cust_id, count(*) FROM orders</code></td>
<td><code>db.orders.aggregate( [</code></td>
<td>For cust_id with multiple records, return the cust_id and the corresponding record count.</td>
</tr>
<tr>
<td></td>
<td>`{ _group: {</td>
<td></td>
</tr>
<tr>
<td></td>
<td>} }</td>
<td></td>
</tr>
</tbody>
</table>

4.4 Aggregation Commands

Aggregation Commands

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate</td>
<td>Performs aggregation tasks (page 7) such as group using the aggregation framework.</td>
</tr>
<tr>
<td>count</td>
<td>Counts the number of documents in a collection.</td>
</tr>
<tr>
<td>distinct</td>
<td>Displays the distinct values found for a specified key in a collection.</td>
</tr>
<tr>
<td>group</td>
<td>Groups documents in a collection by the specified key and performs simple aggregation.</td>
</tr>
<tr>
<td>mapReduce</td>
<td>Performs map-reduce (page 10) aggregation for large data sets.</td>
</tr>
</tbody>
</table>

Aggregation Methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.collection.aggregate()</td>
<td>Provides access to the aggregation pipeline (page 7).</td>
</tr>
<tr>
<td>db.collection.group()</td>
<td>Groups documents in a collection by the specified key and performs simple aggregation.</td>
</tr>
<tr>
<td>db.collection.mapReduce()</td>
<td>Performs map-reduce (page 10) aggregation for large data sets.</td>
</tr>
</tbody>
</table>

4.5 Variables in Aggregation Expressions

Aggregation expressions (page 38) can use both user-defined and system variables.

Variables can hold any BSON type data. To access the value of the variable, use a string with the variable name prefixed with double dollar signs ($$).

If the variable references an object, to access a specific field in the object, use the dot notation; i.e. "$$.<variable>.<field>".

User Variables

User variable names can contain the ascii characters [_a-zA-Z0-9] and any non-ascii character.

User variable names must begin with a lowercase ascii letter [a-z] or a non-ascii character.

System Variables

MongoDB offers the following system variables:

\textsuperscript{22}http://www.mongodb.com/mongodb-and-mysql-compared?jmp=docs
\textsuperscript{23}https://www.mongodb.com/lp/misc/quick-reference-cards?jmp=docs
\textsuperscript{24}https://www.mongodb.com/products/consulting?jmp=docs#database_modernization
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROOT</td>
<td>References the root document, i.e. the top-level document, currently being processed in the aggregation pipeline stage.</td>
</tr>
<tr>
<td>CURRENT</td>
<td>References the start of the field path being processed in the aggregation pipeline stage. Unless documented otherwise, all stages start with CURRENT (page 47) the same as ROOT (page 47). CURRENT (page 47) is modifiable. However, since $\langle field\rangle$ is equivalent to $$\text{CURRENT.}\langle field\rangle$$, re-binding CURRENT (page 47) changes the meaning of $ accesses.</td>
</tr>
<tr>
<td>DESCEND</td>
<td>One of the allowed results of a $\text{redact}$ expression.</td>
</tr>
<tr>
<td>PRUNE</td>
<td>One of the allowed results of a $\text{redact}$ expression.</td>
</tr>
<tr>
<td>KEEP</td>
<td>One of the allowed results of a $\text{redact}$ expression.</td>
</tr>
</tbody>
</table>
